CARING FOR THE CRITICALLY ILL PATIENT

ONLINE FIRST

Daily Sedation Interruption in Mechanically Ventilated Critically Ill Patients Cared for With a Sedation Protocol

A Randomized Controlled Trial

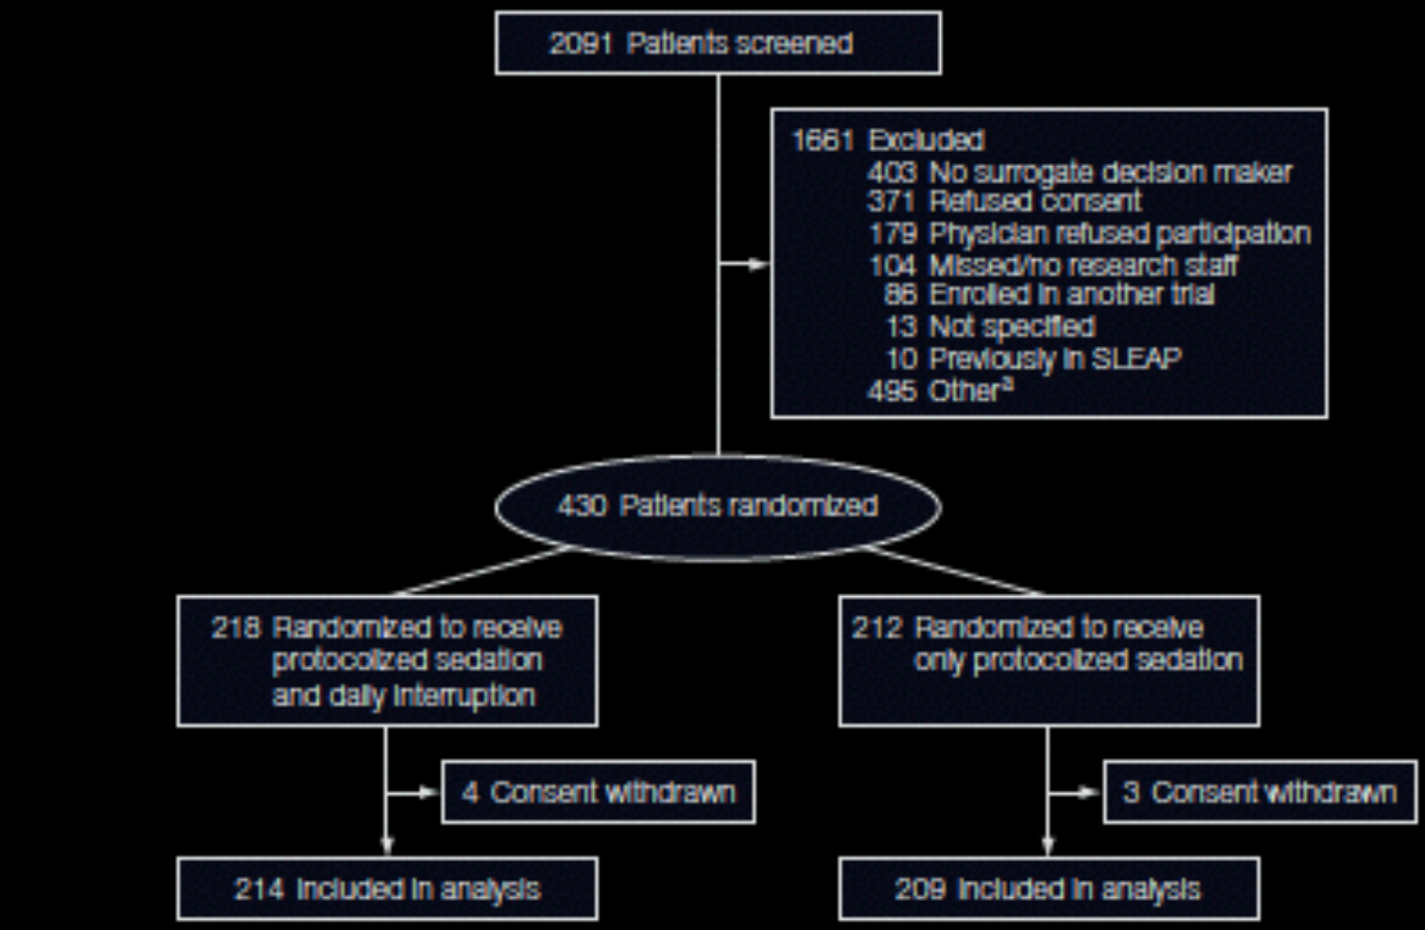
Sangeeta Mehta, MD
Lisa Burry, PharmD
Deborah Cook, MD
Dean Fergusson, PhD
Marilyn Steinberg, RN

Context Protocolized sedation and daily sedative interruption are 2 strategies to minimize sedation and reduce the duration of mechanical ventilation and intensive care unit (ICU) stay. We hypothesized that combining these strategies would augment the benefits.

Objective To compare protocolized sedation with protocolized sedation plus daily sedation interruption in critically ill patients.

Mehta, JAMA 2012

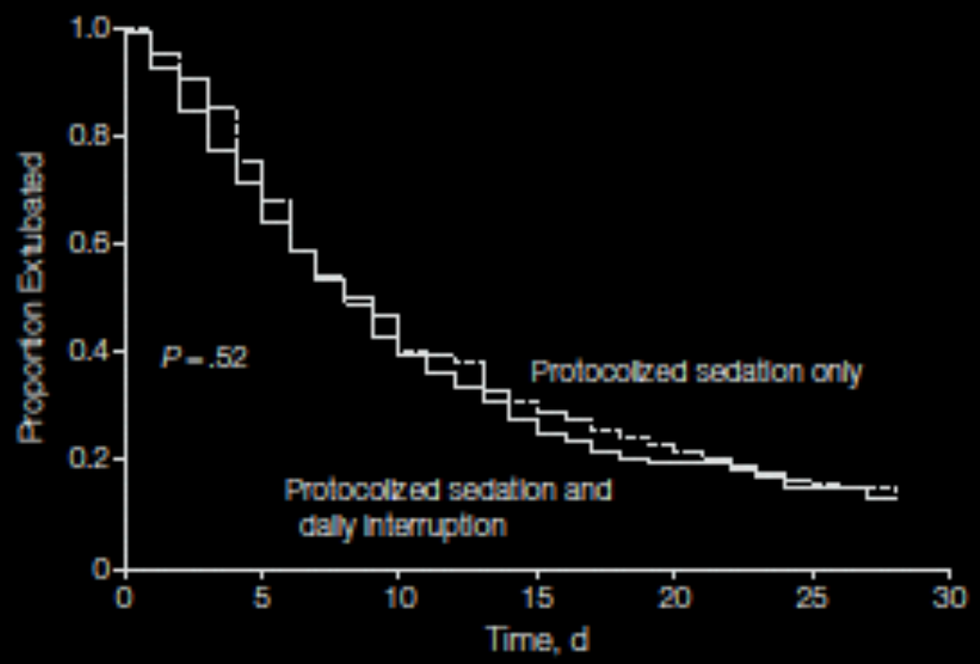
Figure 1. Flow of Patients in the Trial



[a] Other includes 362 patients receiving propofol, 39 with open abdomen or chest, 33 needing ongoing deep sedation (because of a plan to return to the operating room, severe agitation, chronic pain, precarious airway, or hemodynamic instability), and 23 receiving high-frequency ventilation. For the remainder, please see the supplemental eAppendix.

Mehta, JAMA 2012

Figure 2. Kaplan-Meier Curves for Time to Successful Extubation



No. at risk						
Protocolized sedation only	209	146	72	49	34	23
Protocolized sedation and daily interruption	214	140	81	42	28	16

P value calculated from log-rank statistic

Mehta, JAMA 2012

Table 3. Benzodiazepine and Opioid Administration[a]

	Protocolized Sedation and Interruption (n = 214)	Protocolized Sedation (n = 209)	Measure of Effect, Mean Difference (95% CI)	*P* Value
Midazolam equivalents				
Total dose/patient, mg	1087 (4297) 222 (50 to 734)	1038 (4592) 237 (57 to 599)	48.4 (–804.4 to 901.2)	.91
Dose/patient/d, mg	102 (326) 8 (0 to 86)	82 (287) 0 (0 to 50)	19.23 (2.37 to 37.07)	.04
Dose/patient/d, infusion, mg	101 (325) 6 (0 to 86)	82 (287) 0 (0 to 50)	19.22 (1.92 to 36.53)	.03
Dose/patient/d, bolus, mg	0.99 (5.9) 0 (0 to 0)	0.49 (2.65) 0 (0 to 0)	0.50 (0.23 to 0.76)	<.001
Infusion, d	5.73 (6.42) 4 (2 to 7)	5.58 (5.91) 4 (2 to 7)	0.15 (–1.04 to 1.33)	.81
Boluses/d, No.	0.253 (1.145) 0 (0 to 0)	0.177 (0.808) 0 (0 to 0)	0.077 (0.020 to 0.134)	.007
Fentanyl equivalents				
Total dose/patient, µg	18 997 (59 928) 5286 (1512 to 16 437)	13 532 (23 219) 5936 (2056 to 15 236)	5464.6 (–3236.0 to 14 165.2)	.22
Dose/patient/d, µg	1780 (4135) 550 (50 to 1850)	1070 (2066) 260 (0 to 1400)	709.3 (522.0 to 897.7)	<.001
Dose/patient/d, infusion, µg	1664 (4070) 420 (0 to 1725)	984 (2002) 80 (0 to 1260)	679.7 (495.3 to 864.1)	<.001
Dose/patient/d bolus, µg	116 (215) 0 (0 to 100)	86 (169) 40 (0 to 150)	30.13 (19.15 to 41.11)	<.001
Infusion, d	6.44 (6.86) 5 (2 to 9)	6.61 (6.20) 5 (3 to 9)	–0.17 (–1.42 to 1.09)	.79
Boluses/d, No.	2.18 (2.87) 1 (0 to 4)	1.79 (2.67) 0 (0 to 3)	0.395 (0.239 to 0.551)	<.001

Conversion factors: For conversion of lorazepam to midazolam, 1 mg midazolam=0.5 mg lorazepam. For conversion of opioids to fentanyl equivalents, 10 mg morphine=2 mg hydromorphone=0.1 mg fentanyl.

[a]Doses are presented as mean (SD) in the first row and median (interquartile range) in the second row.

Mehta, JAMA 2012

Ramsay Scale

Awake levels

- 1 patient anxious or agitated or both
- 2 patient co-operative, orientated and tranquil
- 3 patient responds to commands only

Asleep levels

- 4 a brisk response
- 5 a sluggish response
- 6 no response

- to a light glabellar tap
  or
- loud auditory stimulus

Ramsay, BMJ 1974

Echelle de sédation-agitation de Richmond (RASS)		
Score	**Terme**	**Description**
+4	**Combatif**	Combatif, danger immédiat envers l'équipe
+3	**Très agité**	Tire, arrache tuyaux et cathéters et/ou agressif envers l'équipe
+2	**Agité**	Mouvements fréquents sans but précis et/ou désadaptation au respirateur
+1	**Ne tient pas en place**	Anxieux ou craintif, mais mouvements orientés, peu fréquents, non vigoureux, non agressifs
0	**Eveillé et calme**	
-1	**Somnolent**	Pas complètement conscient mais reste éveillé avec contact visuel à l'appel (>10s)
-2	**Sédation légère**	Reste éveillé brièvement avec contact visuel à l'appel (<10s)
-3	**Sédation modérée**	N'importe quel mouvement à l'appel (Ex. ouverture des yeux), mais pas de contact visuel
-4	**Sédation profonde**	Aucun mouvement à l'appel, n'importe quel mouvement à la stimulation physique (friction nociceptive de l'épaule ou du sternum)
-5	**Non réveillable**	Aucun mouvement ni à l'appel, ni à la stimulation physique (friction non nociceptive de l'épaule ou du sternum)

Ely, JAMA 2003

Score d' « Adaptation to Intensive Care Environnement » (ATICE)									
Domaine conscience				***Domaine tolérance***					
Eveil (gradué de 0 à 5)		**Compréhension** (somme des réponses cotées 1)		**Calme** (gradué de 0 à 3)		**Adaptation au respirateur** (somme des éléments cotés 1)		**Relaxation de la face** (graduée de 0 à 3)	
Yeux fermés, aucune mimique	**0**	«Ouvrez (ou fermez) les yeux»	**1 pt**	Agitation majeure, dangereuse pour le patient	**0**	Pas de blocage de la phase inspiratoire du respirateur par le patient	**1 pt**	Grimace permanente	**0**
Yeux fermés, mimique lors de la stimulation douloureuse forte	**1**	«Ouvrez la bouche»	**1 pt**	Agitation non calmée par les commandes verbales	**1**	Pas de polypnée > 30	**1 pt**	Grimace provoquée sévère	**1**
Ouverture des yeux après stimulation douloureuse forte	**2**	«Regardez par ici»	**1 pt**	Agitation calmée aux commandes verbales	**2**	Pas de toux	**1 pt**	Grimace provoquée modérée	**2**
Ouverture des yeux après stimulation douloureuse légère	**3**	«Faites oui avec la tête»	**1 pt**	Calme	**3**	Pas de tirage	**1 pt**	Visage relaxé	**3**
Ouverture des yeux après stimulation verbale	**4**	«Fermez les yeux et ouvrez la bouche»	**1 pt**

Sedation and analgesia in intensive care (with the exception of new-born babies)

Special Article

Clinical Practice Guidelines for the Management of Pain, Agitation, and Delirium in Adult Patients in the Intensive Care Unit

Assess and Treat	Statements and Recommendations
PAIN	• Pain assessment should be routinely performed in all ICU patients (1B). • Self report is preferred over the use of behavioral pain scales to assess pain in ICU patients who are able to communicate (B). • The BPS and CPOT are the most valid and reliable behavioral pain scales for use in ICU patients who cannot communicate (B). • Vital signs should not be used alone to assess pain, but they may be used adjunctively for pain assessments (2C). • Preemptively treat chest tube removal with either analgesics and/or non-pharmacologic therapy (1C). • Suggest preemptively treating other types of procedural pain with analgesic and/or non-pharmacologic therapy (2C). • Use opioids as first line therapy for treatment of non-neuropathic pain (1C). • Suggest using non-opioid analgesics in conjunction with opioids to reduce opioid requirements and opioid-related side effects (2C). • Use gabapentin or carbamazepine, in addition to intravenous opioids, for treatment of neuropathic pain (1A). • Use thoracic epidural for postoperative analgesia in abdominal aortic surgery patients (1B). • Suggest thoracic epidural analgesia be used for patients with traumatic rib fractures (2B).

Assess and Treat	Statements and Recommendations
AGITATION	• Depth and quality of sedation should be routinely assessed in all ICU patients (1B). • The RASS and SAS are the most valid and reliable scales for assessing quality and depth of sedation in ICU patients (B). • Suggest using objective measures of brain function to adjunctively monitor sedation in patients receiving neuromuscular blocking agents (2B). • Use EEG monitoring either to monitor non-convulsive seizure activity in ICU patients at risk for seizures, or to titrate electrosuppressive medication to achieve burst suppression in ICU patients with elevated intracranial pressure (1A). • Target the lightest possible level of sedation and/or use daily sedative interruption (1B). • Use sedation protocols and checklists to facilitate ICU sedation management (1B). • Suggest using analgesia-first sedation for intubated and mechanically ventilated ICU patients (2B). • Suggest using non-benzodiazepines for sedation (either propofol or dexmedetomidine) rather than benzodiazepines (either midazolam or lorazepam) in mechanically ventilated adult ICU patients (2B).

Assess and Treat	Statements and Recommendations
DELIRIUM	• Delirium assessment should be routinely performed in all ICU patients (1B). • The CAM-ICU and ICDSC delirium monitoring tools are the most valid and reliable scales to assess delirium in ICU patients (A). • Mobilize ICU patients early when feasible to reduce the incidence and duration of delirium, and to improve functional outcomes (1B). • Promote sleep in ICU patients by controlling light and noise, clustering patient care activities, and decreasing stimuli at night (1C). • Avoid using rivastigmine to reduce the duration of delirium in ICU patients (1B). • Suggest avoiding the use of antipsychotics in patients who are at risk for torsades de pointes (2B). • Suggest not using benzodiazepines in ICU patients with delirium unrelated to ETOH/benzodiazepine withdrawal (2B).

New Idea to Cut I.C.U. Trauma: Get Patients Up, Tubes and All

By GINA KOLATA

For years, doctors thought they had done their jobs if patients came out of an intensive care unit alive.

Now, though, researchers say they are alarmed by what they are finding as they track patients for months or years after an I.C.U. stay. Patients, even young ones, can be weak for years. Some have difficulty thinking and concentrating or have post-traumatic stress disorder and terrible memories of nightmares they had while heavily sedated.

While patients may be suffering lingering effects from illnesses that brought them to the I.C.U., researchers are increasingly convinced that spending days, weeks or months on life support in the units can elicit unexpected, long-lasting effects.

So now some I.C.U.'s are trying what seems like a radical solution: reducing sedation levels and getting patients up and walking even though they are gravely ill, complete with feeding tubes, intravenous lines and tethers to ventilators.

Even a few days in an I.C.U. can be physically devastating immediately afterward, said Dr. Naeem Ali of Ohio State Universi-

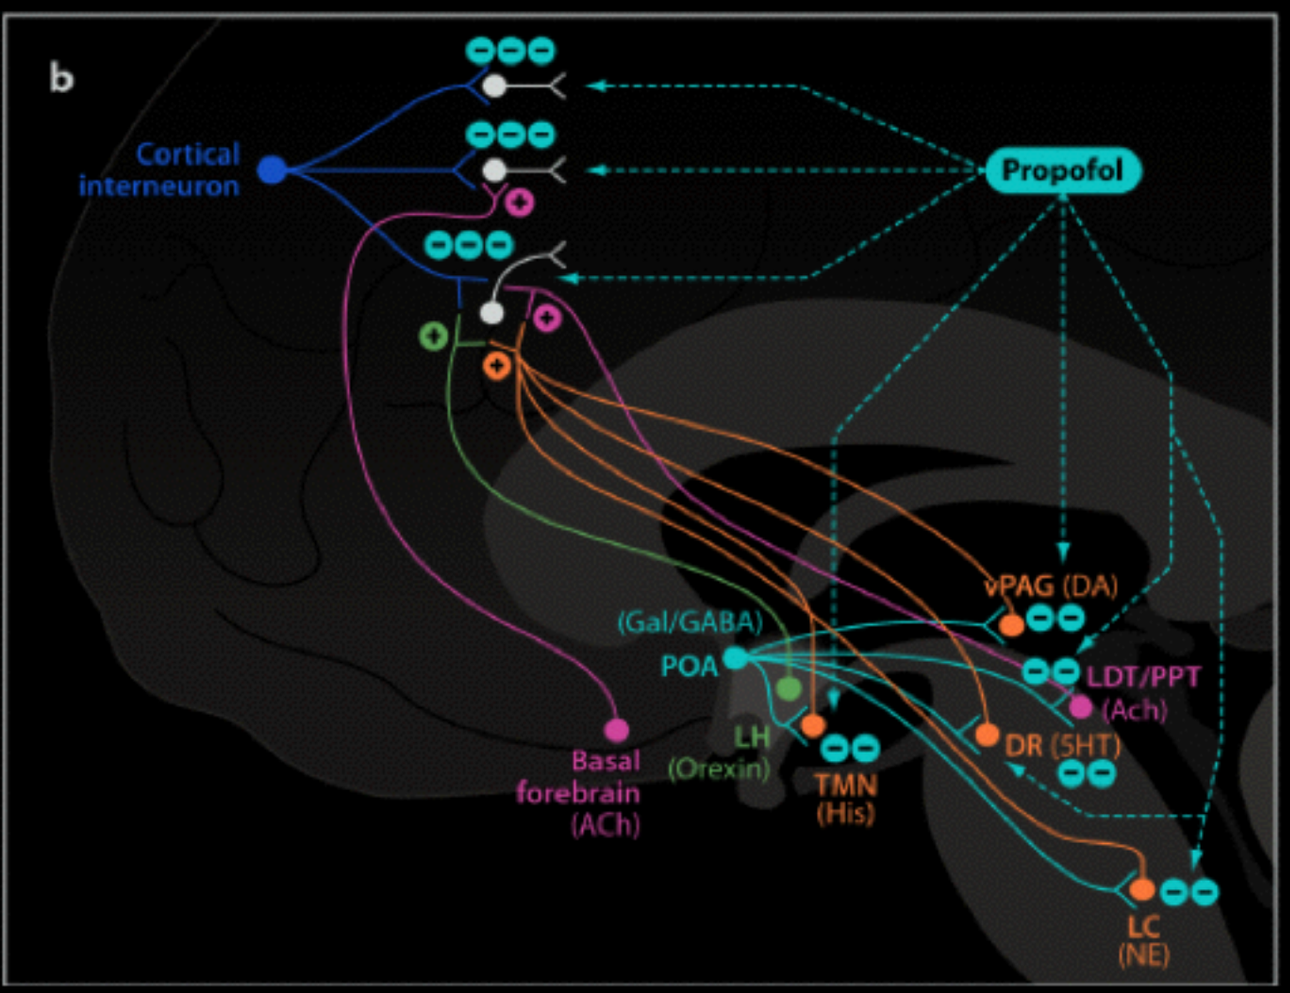
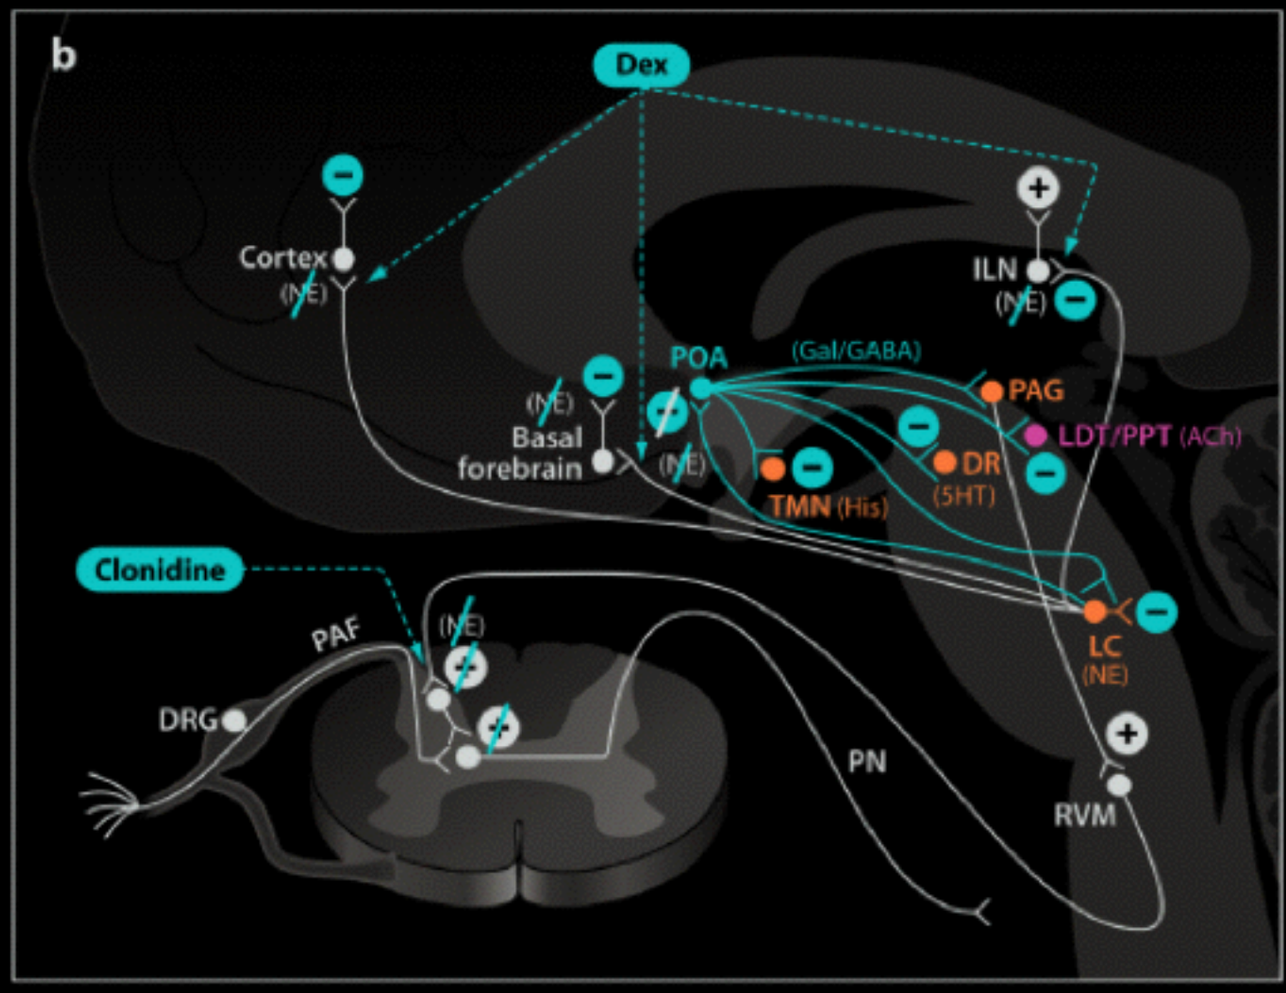
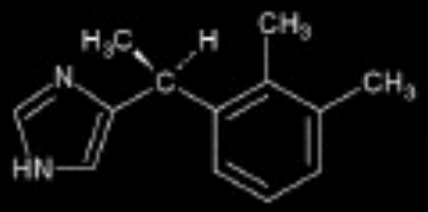
Dexmédétomidine



GABA



α2 agoniste



Propriétés pharmacologiques

- Agoniste des récepteurs α2-adrénergiques (affinité x 8/ clonidine): inhibition de la libération de noradrénaline (locus coeruleus)
- Effet sédatif, anxiolytique et analgésique **indépendant du récepteur GABA**
- Effet sympatholytique: ↓PA ↓FC
- Efficace dans le syndrome de sevrage morphinique
- **Pas de dépression respiratoire**
- Liaison protéines 94 %; Métabolisme hépatique (CYP450)-élimination rénale (métabolites)

Pharmacocinétique

Pharmacocinétique linéaire; $t_{1/2}\alpha$=6 min; Vd=118 L $t_{1/2}$= 2 h

Pas d'influence de l'âge et du sexe

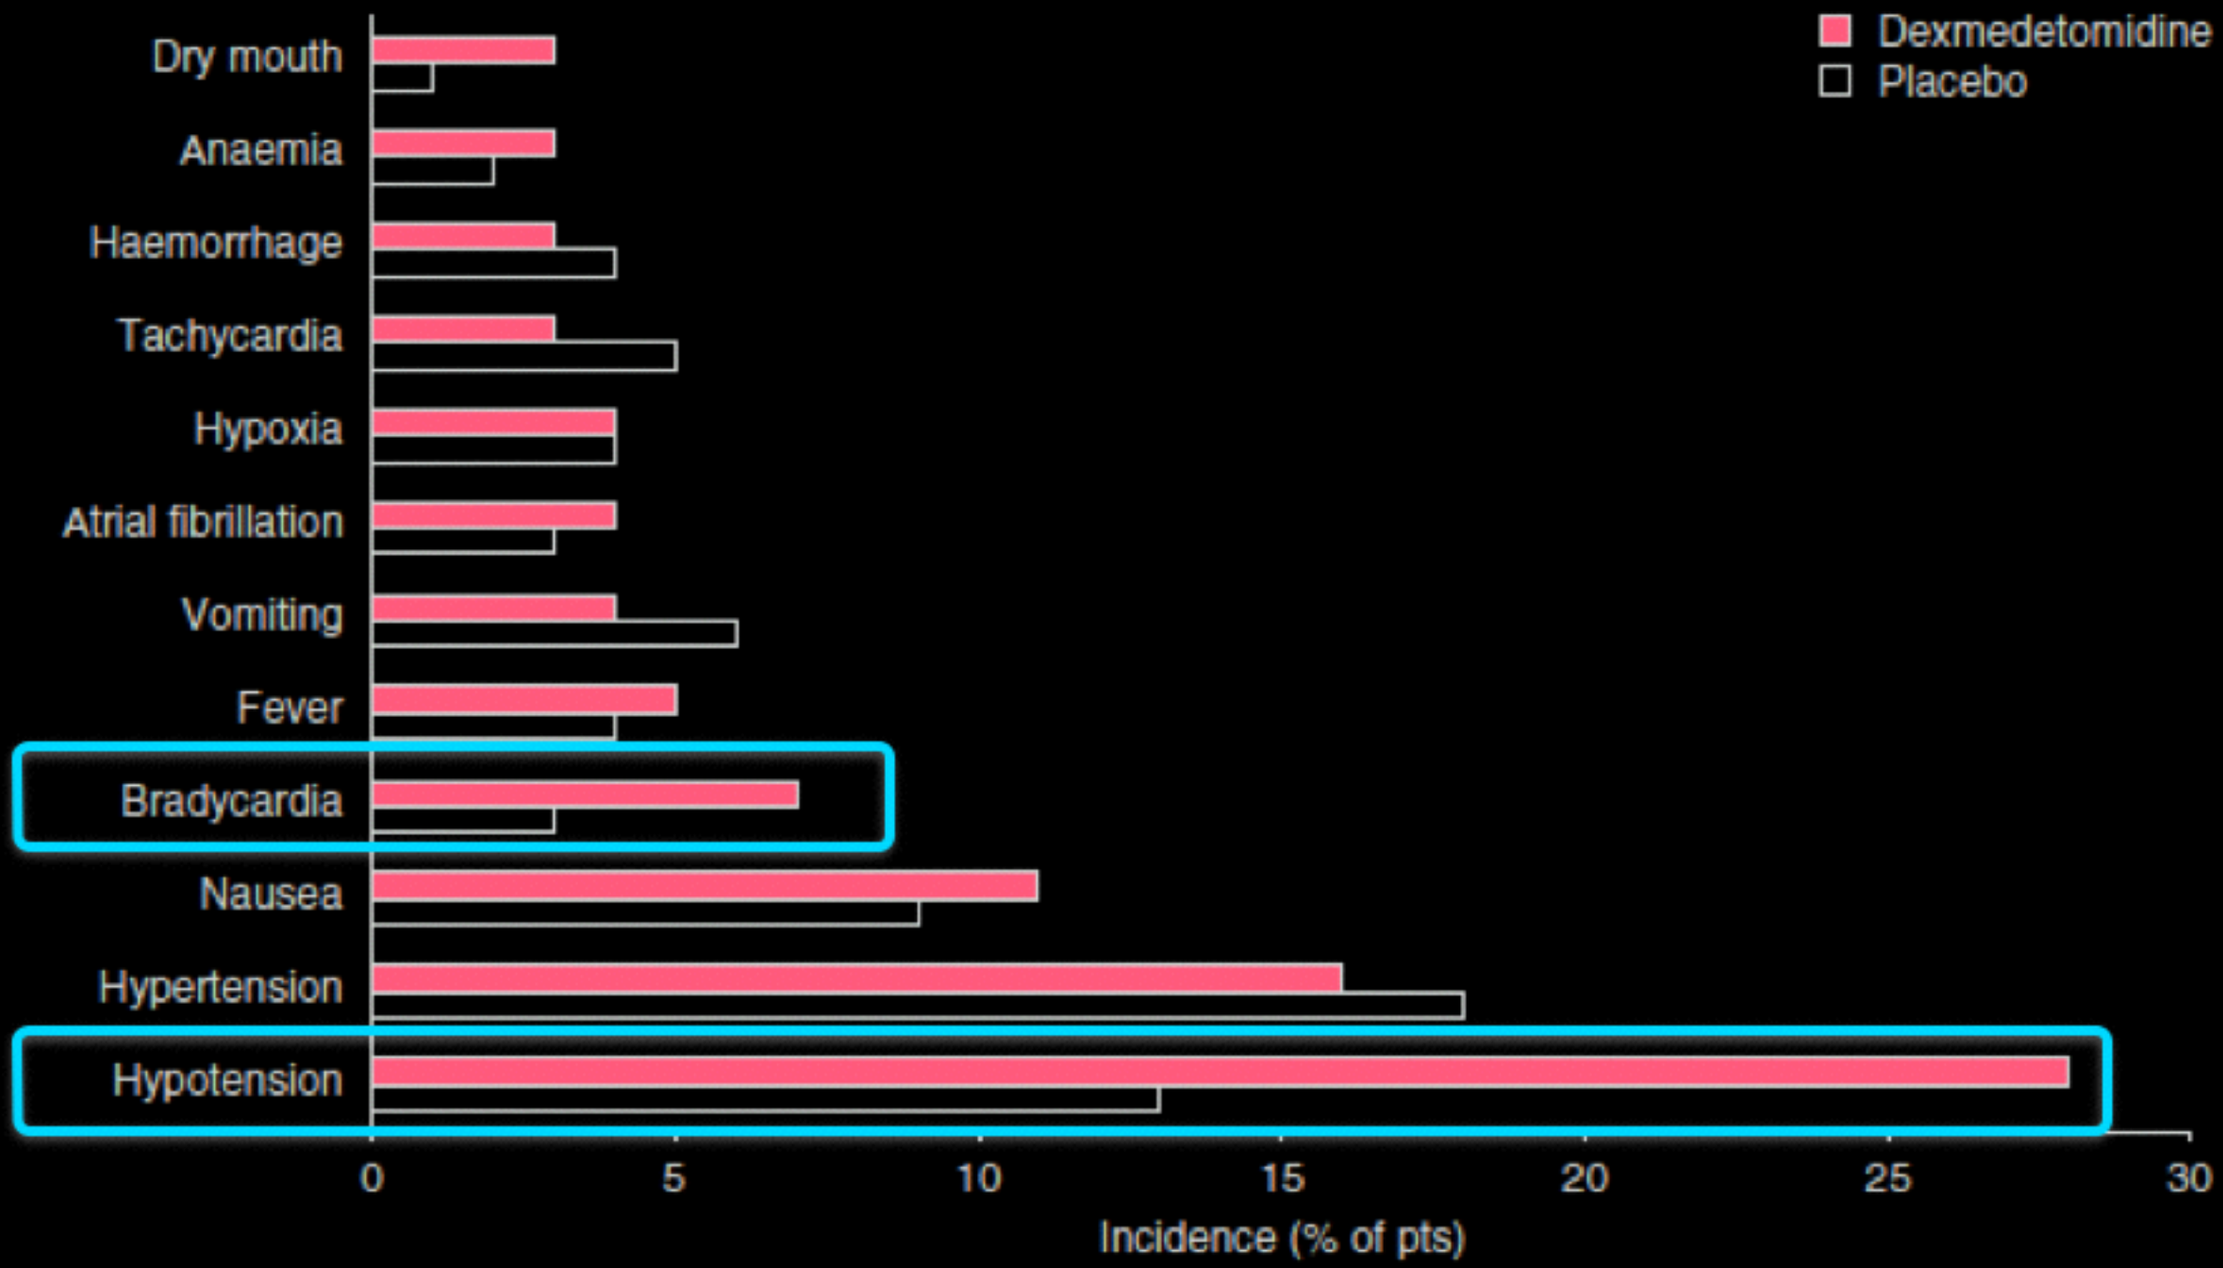
Pas de modification de la ½ vie en cas d'insuffisance rénale sévère

Diminution de la clairance en cas d'insuffisance hépatique

Pas d'interaction médicamenteuse significative

Dose: *Pas de bolus*; 0,2 à 1,4 µg/kg/heure

Effets secondaires



SM Hoy et al. Drugs 2011

Contre-indications

- Hypersensibilité à la substance active
- Bloc cardiaque avancé (niveau 2 ou 3) sauf si pacemaker.
- Hypotension non-contrôlée.
- Pathologies cérébrovasculaires aiguës.

Population à risque

- Sujets agés: Aucun ajustement de la dose n'est nécessaire chez le sujet âgé.

- Insuffisants rénaux: Aucun ajustement de la dose n'est nécessaire.

- Insuffisants hépatiques: Dexdor est métabolisé au niveau hépatique et devrait être utilisé avec précaution chez les insuffisant hépatique.
