Quel est le risque de plainte après ALR ?

Cheney, FW: High-Severity Injuries Associated with Regional Anesthesia in the 1990s. ASA Newsletter 65(6): 6-8, 2001

- The ASA Closed Claims Project database consisted of **4.723 closed malpractice claims** retrieved from 35 insurance organizations that insured approximately **14.500 anesthesiologists**
- Of the total database, 67% (3.180) of the claims are associated with general anesthesia and **24%(1.133)** are associated with the use of **regional anesthesia**.
- Of claims where the injuries occurred in the 1990s, **death** occurred in 25% of those associated with general anesthesia and **10%** of those associated **with regional anesthesia**.
- Focusing on claims where the injury occurred in the 1990s, **claims associated with regional anesthesia are more likely to be of a lower severity** than those associated with general anesthesia

Neurological Complications After Regional Anesthesia: Contemporary Estimates of Risk

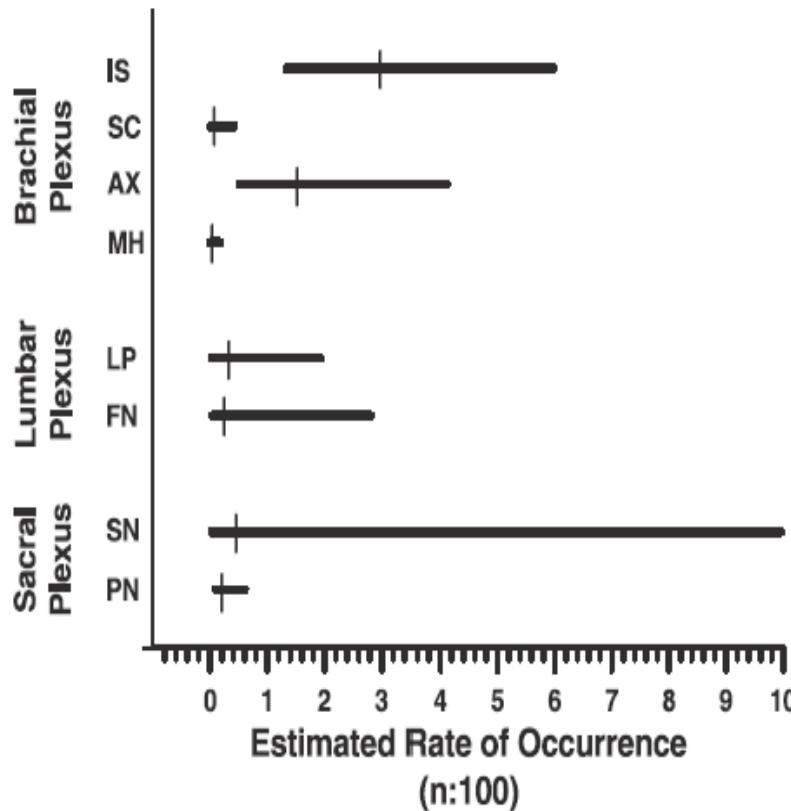

[Anesth Analg 2007;104:965-74]

Richard Brull, MD, FRCPC

Colin J. L. McCartney, MBChB,
FRCA, FFARCSI, FRCPC

Vincent W. S. Chan, MD, FRCPC

Hossam El-Beheiry, MBBCh, PhD,
FRCPC

CONCLUSIONS: Our review suggests that the rate of neurological complications after central nerve blockade is <4:10,000, or 0.04%. The rate of neuropathy after PNB is <3:100, or 3%. However, permanent neurological injury after RA is rare in contemporary anesthetic practice.

The limit of US: resolution = 1mm

Incidence and Effects of Unintentional Intraneural Injection During Ultrasound-Guided Subgluteal Sciatic Nerve Block

(Reg Anesth Pain Med 2012;

Kaoru Hara, MD, Shinichi Sakura, MD, Naomi Yokokawa, MD, and Saki Tadenuma, MD

Conclusions: Unintentional intraneural injection occurred at an incidence rate of 16.3% for the ultrasound-guided subgluteal approach to the sciatic nerve. Intraneural injection of mepivacaine or ropivacaine hastened the onset of blockade but did not affect block duration, and it did not result in clinical neural injury in our small sample of patients.

Incidence of unintentional intraneural injection and postoperative neurological complications with ultrasound-guided interscalene and supraclavicular nerve blocks*

Anaesthesia, 2011, **66**, pages 168–174

S. S. Liu,¹ J. T. YaDeau,² P. M. Shaw,³ S. Wilfred,⁴ T. Shetty⁵ and M. Gordon⁶

It is proposed that ultrasound guidance decreases the risk of intraneural injection and associated postoperative neurological complications. However, the incidence of unintentional intraneural injection with ultrasound is unknown. Two hundred and fifty-seven patients were enrolled in a prospective, single-blind observational study. All patients underwent a pre-operative neurological examination before ambulatory shoulder arthroscopy with sedation and ultrasound-guided interscalene or supraclavicular block. Patients were followed up at 1 week and at 4–6 weeks postoperatively. Two blinded anaesthesiologists viewed the same video of the ultrasound image during the block offline to determine intraneural trespass. Intraneural injection occurred in 42 patients (17%; 95% CI 12–22%). No patient suffered from postoperative neurological complications (0%; 95% CI 0–1.6%) at follow-up.

TABLE 5. Immediate and Delayed Complications According to Nerve Localization Technique

Complication	Nerve Localization Technique				Total (n = 8189)
	Nerve Stimulation (n = 2507)	Ultrasound (n = 5141)	Other (n = 541)		
Local anesthetic toxicity	1.2 (0.25–3.5)	0.8 (0.2–2.0)*	1.8 (0.05–10.3)	0.98 (0.42–1.9)	
Unintentional vascular puncture†	13.9 (8.2–21.9)	5.1 (3.0–8.1)‡	2.3 (0.06–12.8)	7.2 (5.1–10.0)	
Unintended paresthesia†	10.8 (5.9–18.1)	20.5 (15.9–25.9)*	2.3 (0.06–12.8)	16.8 (13.4–20.8)	
Late neurologic deficit	0.8 (0.1–2.9)	0.2 (0.005–1.1)*	—	0.4 (0.08–1.1)	
Long-term neurologic deficit	0.4 (0.01–2.2)	0.2 (0.05–1.1)*	—	0.2 (0.03–0.9)	

Data are presented as n/1000 (95% CI) procedures.

Ultrasound includes ultrasound used as the sole technology and combined ultrasound and nerve stimulation. *Other* comprises techniques not using nerve stimulation or ultrasound technology.

*Not statistically significant.

†Reduced total cohort (n = 4991), for nerve stimulation (n = 1297), ultrasound (n = 3260), and other (n = 434).

‡Indicates a statistically significant difference ($P = 0.001$; Poisson regression) between ultrasound and nerve stimulation and other techniques.

Permanent complications after peripheral nerve/plexus blockade are uncommon. The origin of neurologic symptoms/signs in the perioperative period is most likely unrelated to PNB.

Despite changes in technique over the last decade, the reported incidence of nerve injury related to PNB has not changed.

Pathophysiology and Etiology of Nerve Injury Following Peripheral Nerve Blockade

Richard Brull, MD, FRCPC,* Admir Hadzic, MD, PhD,† Miguel A. Reina, MD, PhD,‡
and Michael J. Barrington, PhD, MBBS, FANZCA§

Reg Anesth Pain Med 2015;40: 479–490

Nerve localization techniques

- There are no human data to support the superiority of one nerve localization technique over another with regard to reducing the likelihood of PNI.^{99,127,137} (Class I)
- Presence of an evoked motor response at a current of <0.5 (0.1 ms) indicates intimate needle-nerve relationship, needle-nerve contact, or an intraneuronal needle placement.^{59,60,104,113} (Class I)
- Absence of a motor response at current of up to 1.8 mA does not exclude needle-nerve contact or intraneuronal needle placement.^{103,104} (Class I)
- Animal data have linked high injection pressures to subsequent fascicular injury, but there are no human data that confirm or refute the effectiveness of injection pressure monitoring for limiting PNI.^{18,109} (Class II)
- Injection pressure monitoring can detect needle-nerve contact for interscalene brachial plexus block.¹²¹ (Class I)
- The common practice of subjectively assessing injection pressure by “hand feel” is inaccurate.¹¹⁸ (Class I)
- Ultrasound can detect intraneuronal injection.^{105,110} (Class I)
- Current ultrasound technology does not have adequate resolution to discern between an interfascicular and intrafascicular injection.^{104,110,138} (Class I)
- Adequate images of needle-nerve interface are not consistently obtained by all operators and in all patients.^{57,128} (Class I)

Neuropathies : Regional anaesthesia or other causes?

Surgery	Attempt	Incidence (%)
Total hip arthroplasty	Sciatic nerve	2 – 4 %
Total knee arthroplasty	Fibular nerve	1 – 6 %
Shoulder arthroplasty	Brachial plexus	3 %
Humerus fracture	Radial nerve	18 %
Shoulder's arthroscopy	Axillary nerve	4 %
Elbow arthroplasty	Ulnar nerve	16 %

“Pre-existing peripheral neuropathy

- **Patients with chronic diabetes mellitus**, severe peripheral vascular disease, multiple sclerosis, or previous exposure to chemotherapy (e.g., cisplatin or vincristine) may have clinical or subclinical evidence of a pre-existing peripheral neuropathy.

Peripheral nerve block may theoretically increase the risk of new or progressive postoperative neurologic complications in these patients.

However, existing data can neither confirm nor refute this theory in clinical practice. Under these clinical conditions, a careful risk-to-benefit assessment of regional anesthesia to alternative perioperative anesthesia and analgesia techniques should be considered. (Class II)”

Results: The epineurium, perineurium, fascicles, endoneurium, and vessels were identified in each sample. In both the short-beveled and the Whitacre samples, all fascicles along with the surrounding perineurium were intact. In both the Tuohy and the Quincke samples, obvious transection of fascicles and disruption of the perineurium were observed.
